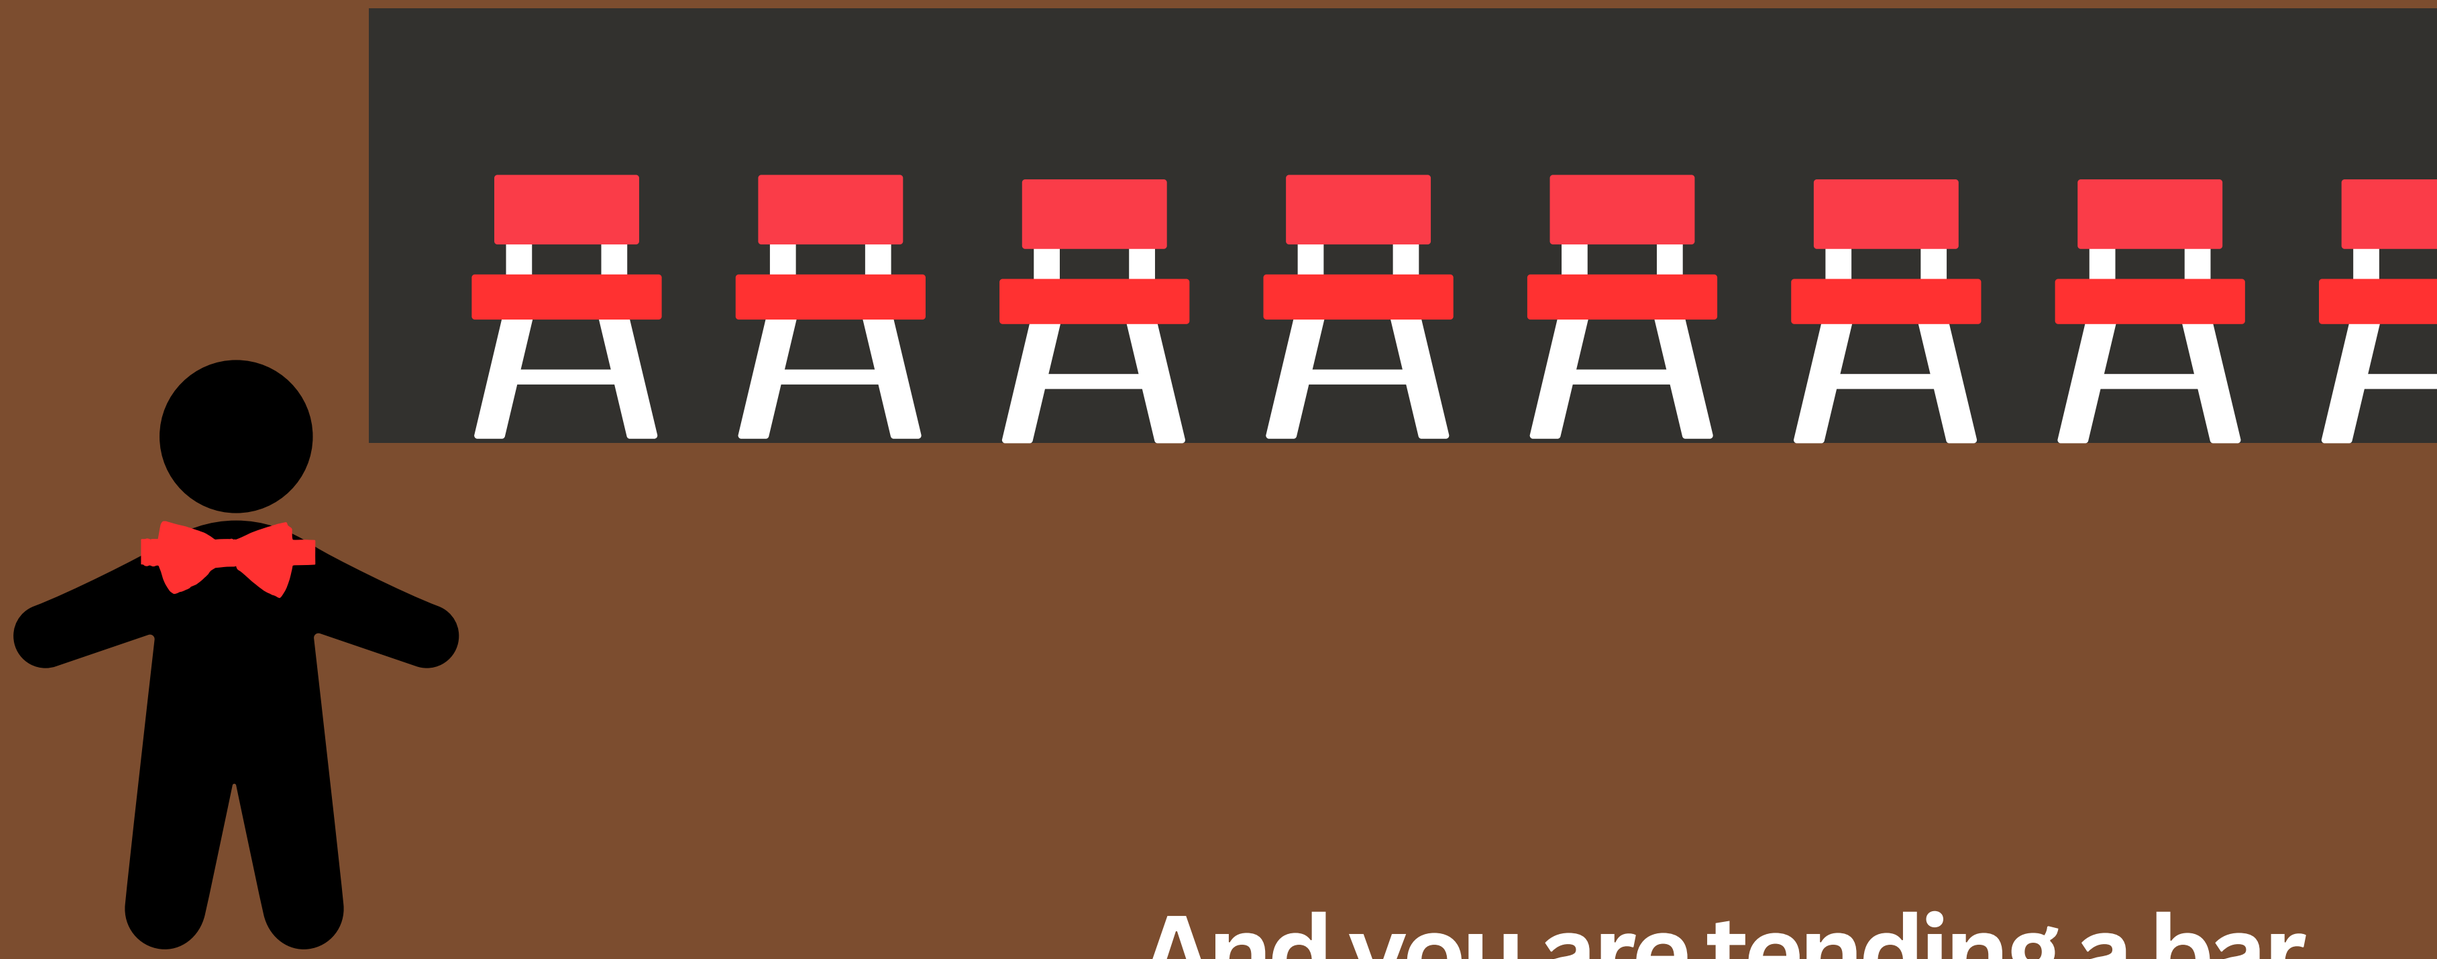
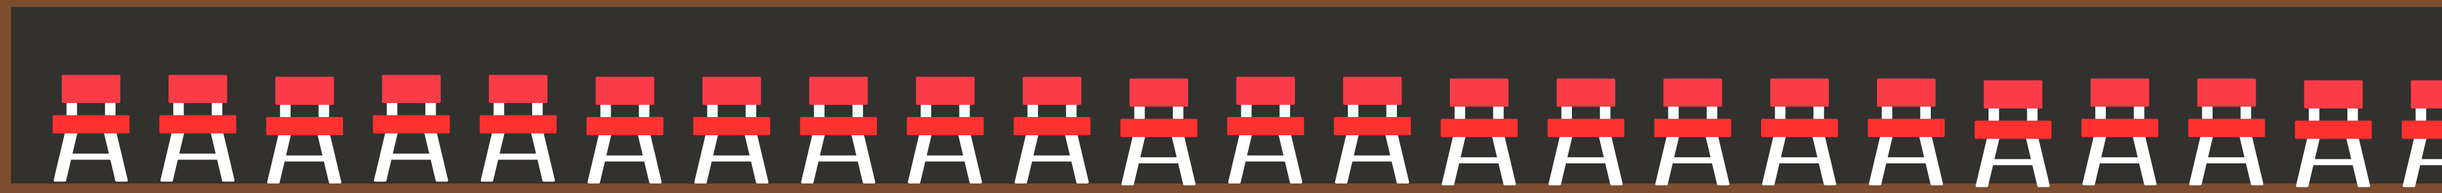
Heap Allocator

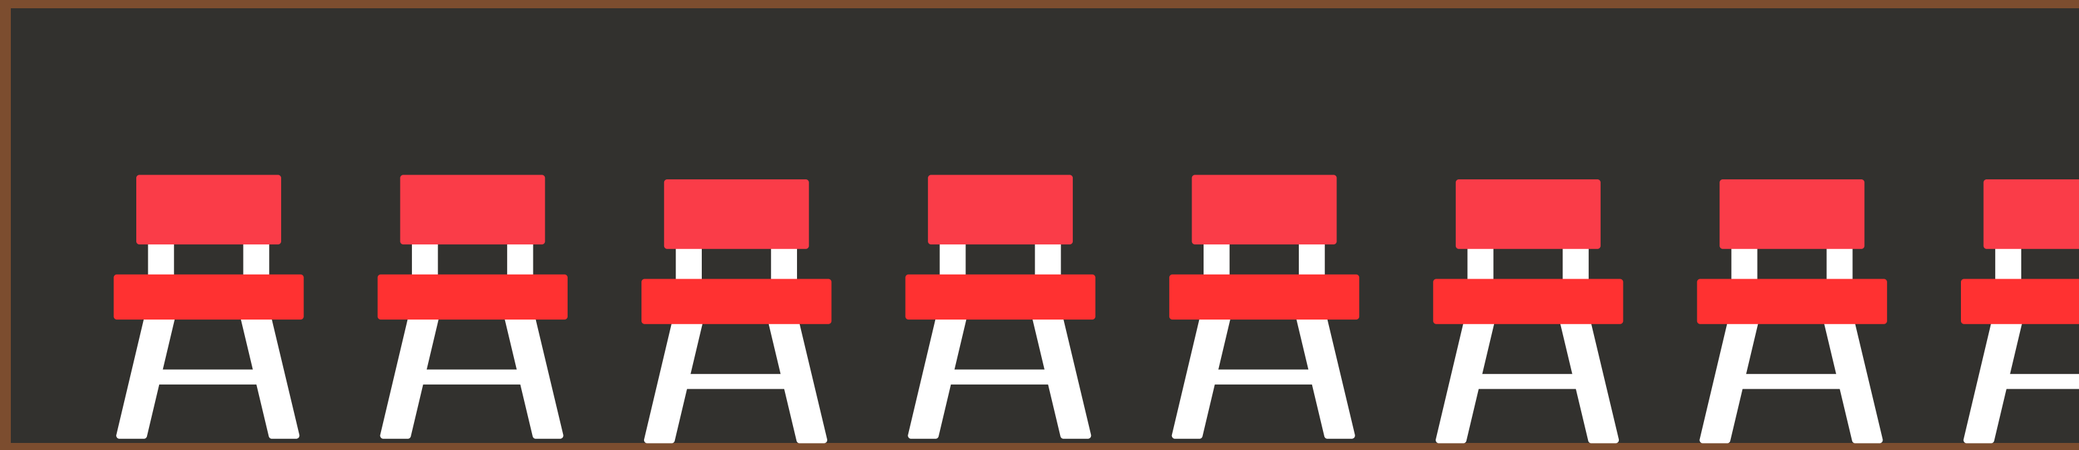
Imagine you are a bartender

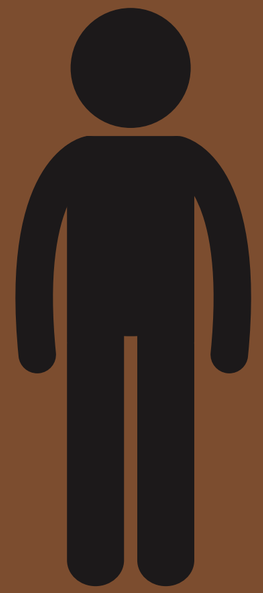


And you are tending a bar...

A really long bar...

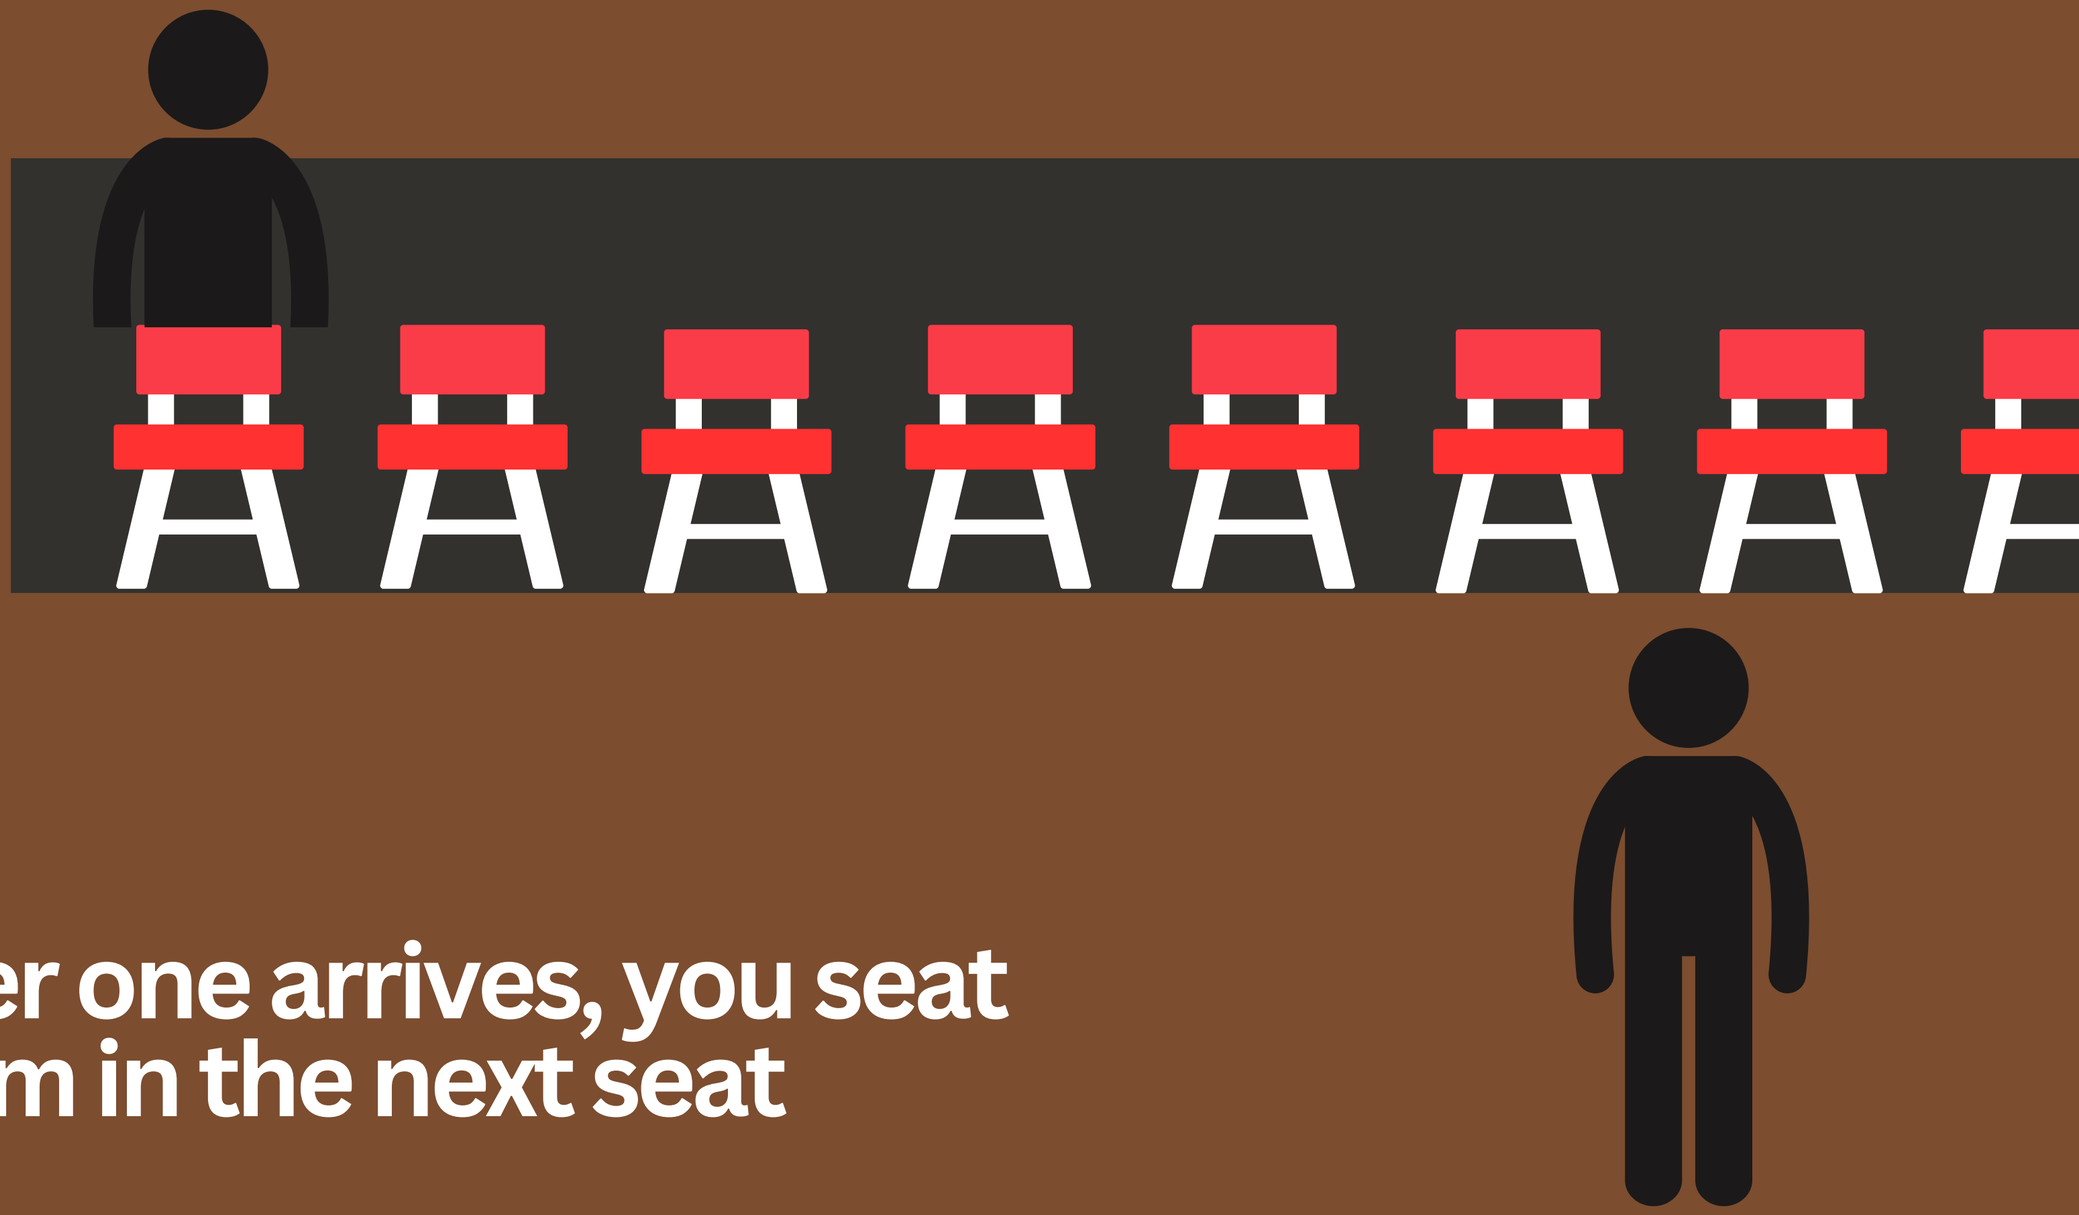






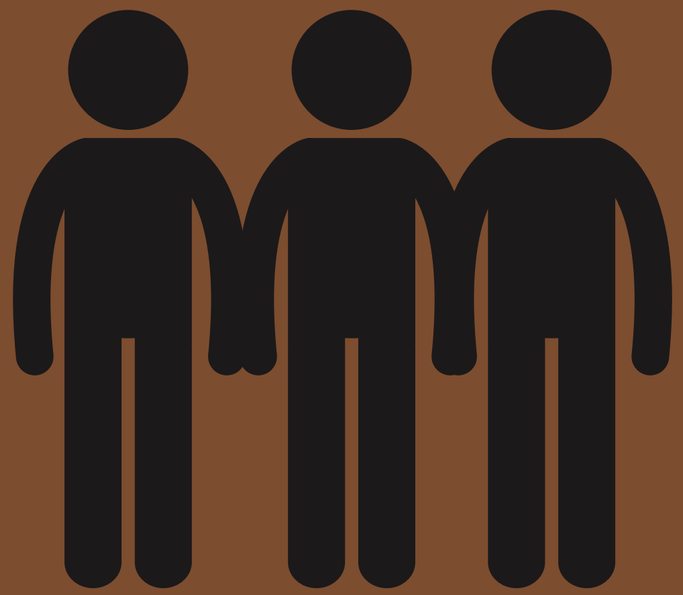
Customers arrive and need to be seated

When 1 customer arrives, you can seat them at the first available seat

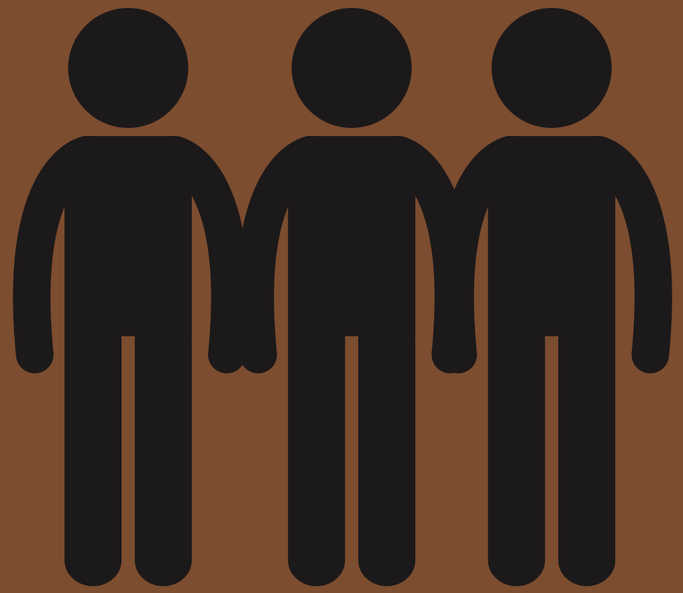


If another one arrives, you seat them in the next seat

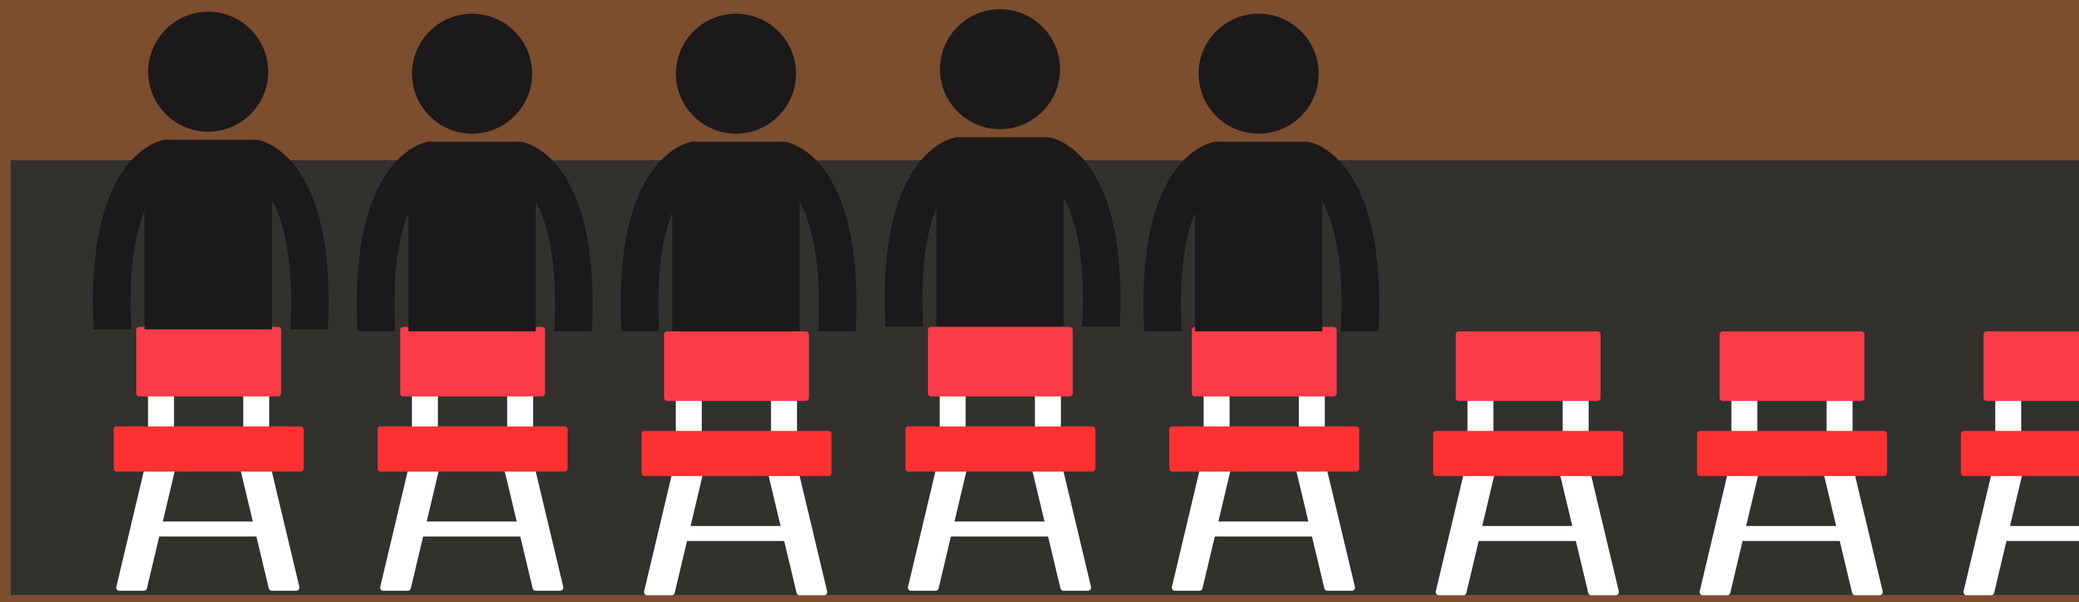
Easy peasy!



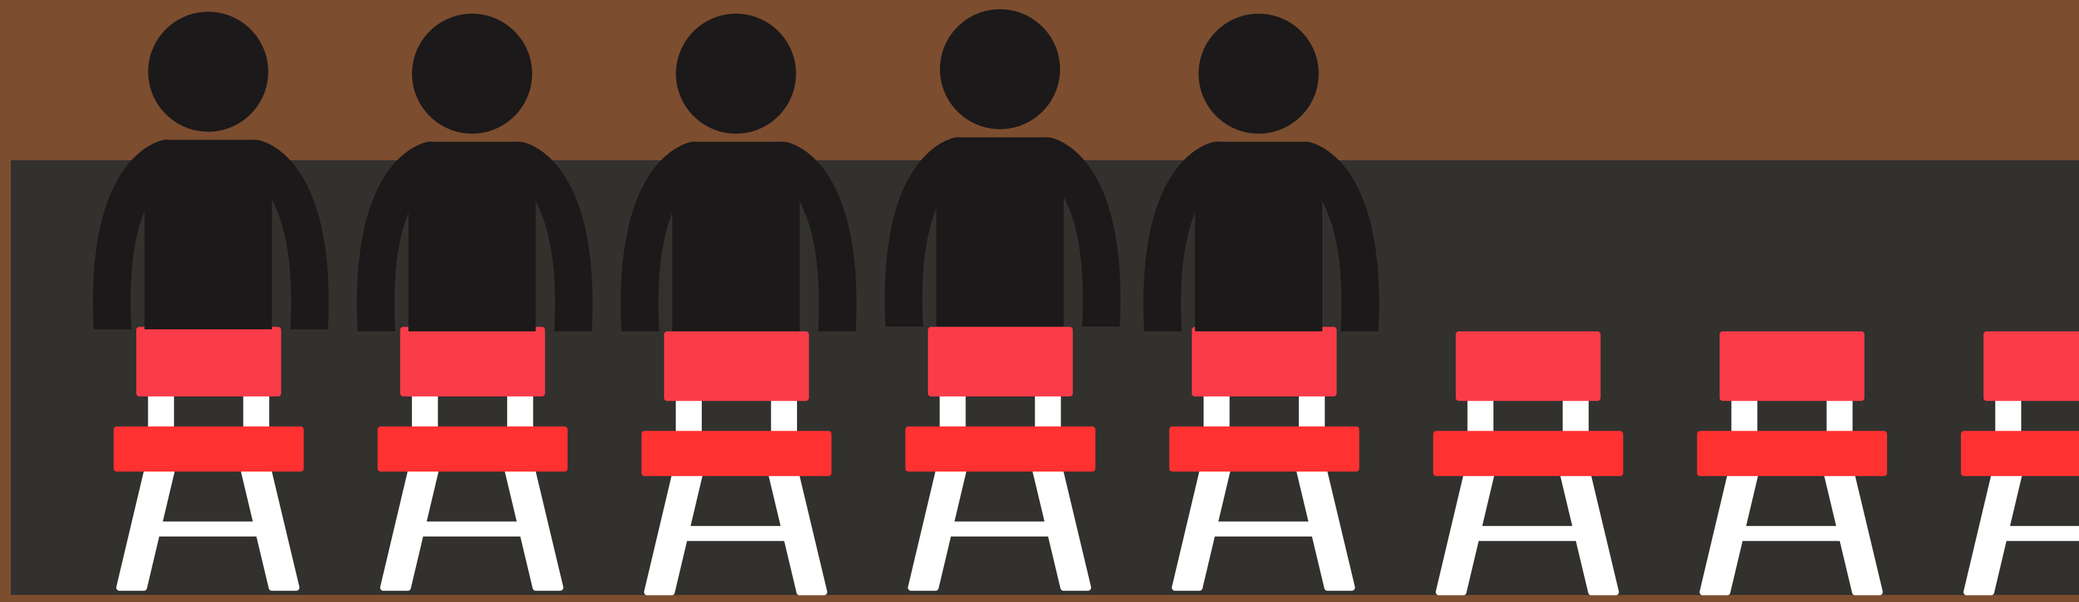
Sometimes they come in groups



Obviously they want to sit together

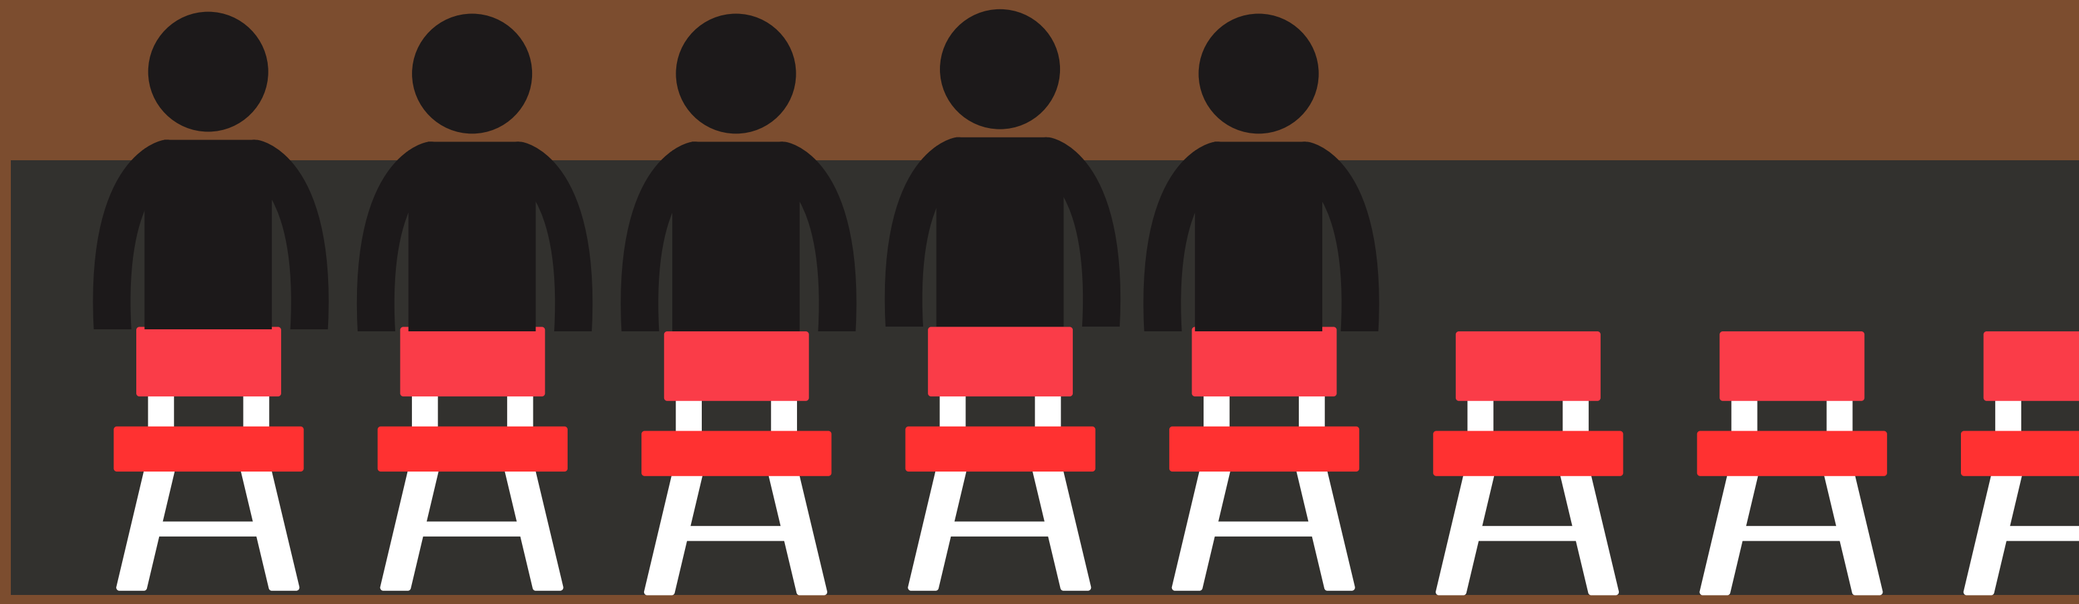


So you seat them together

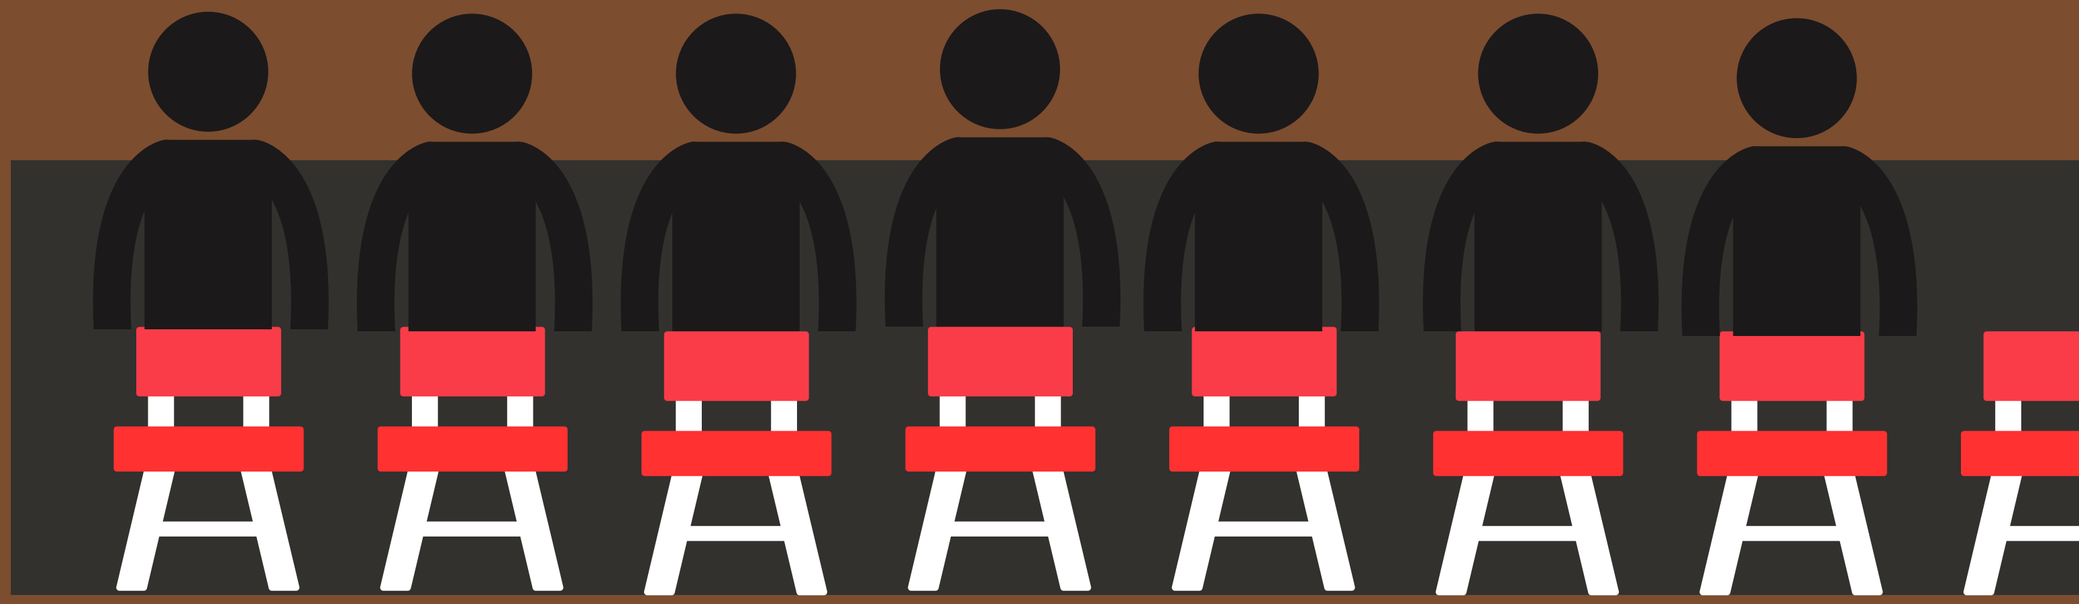


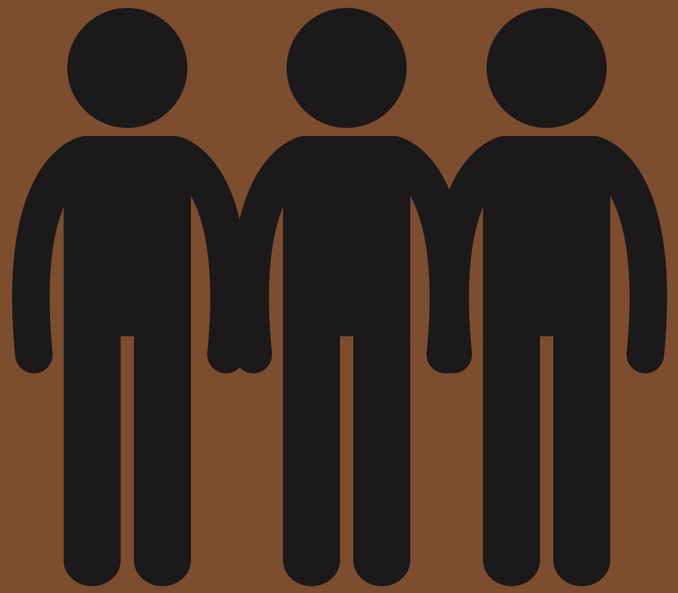
People should be seated coniguously!

So you seat them together

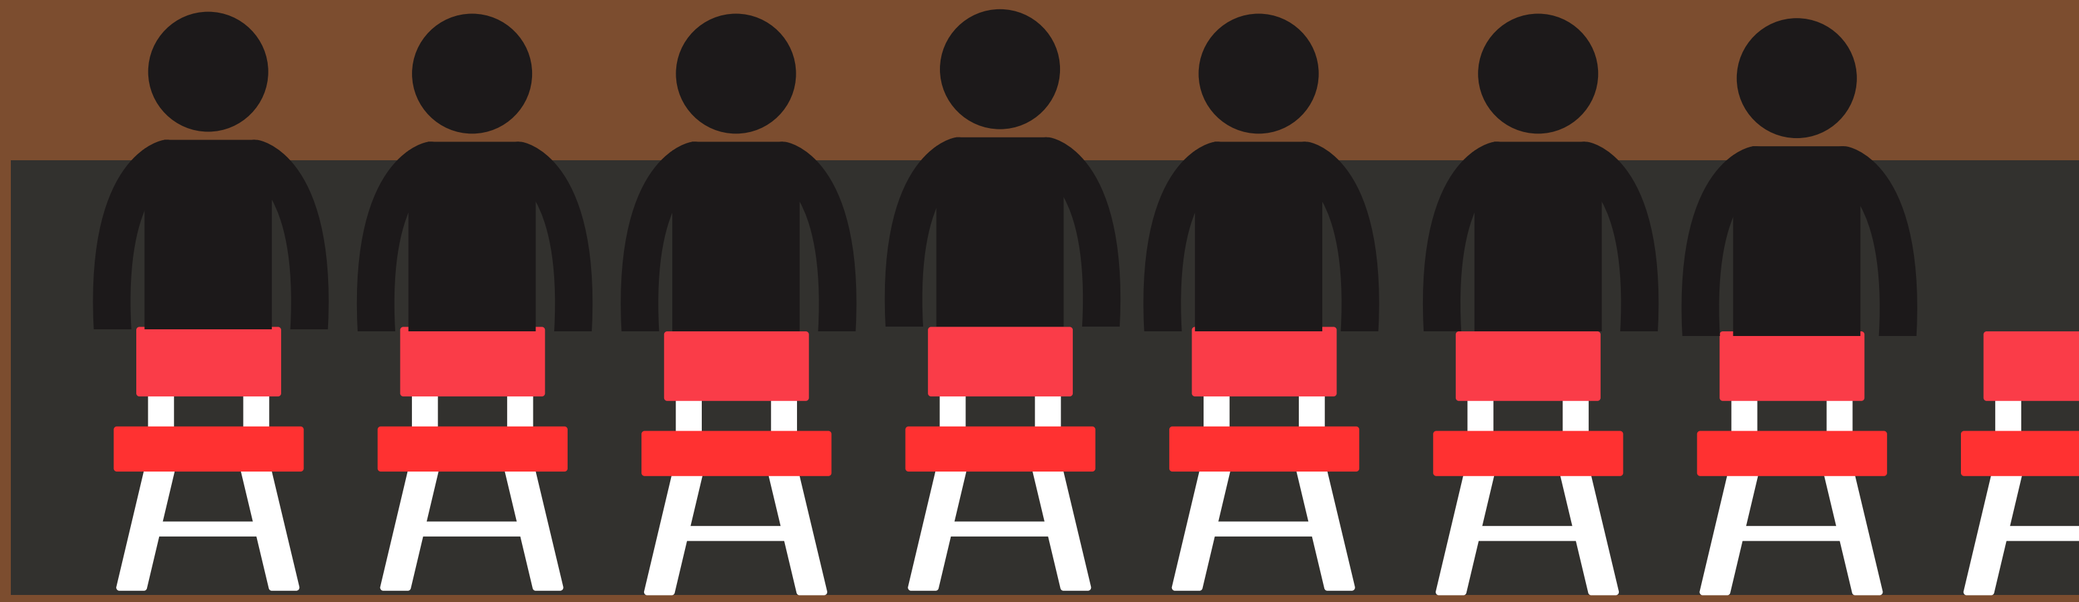


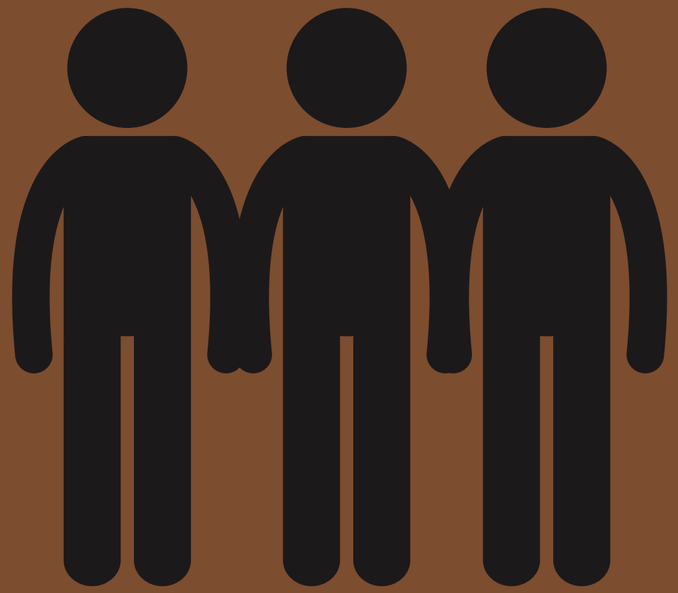
Because your bar is very long, you can continue to seat people at the end





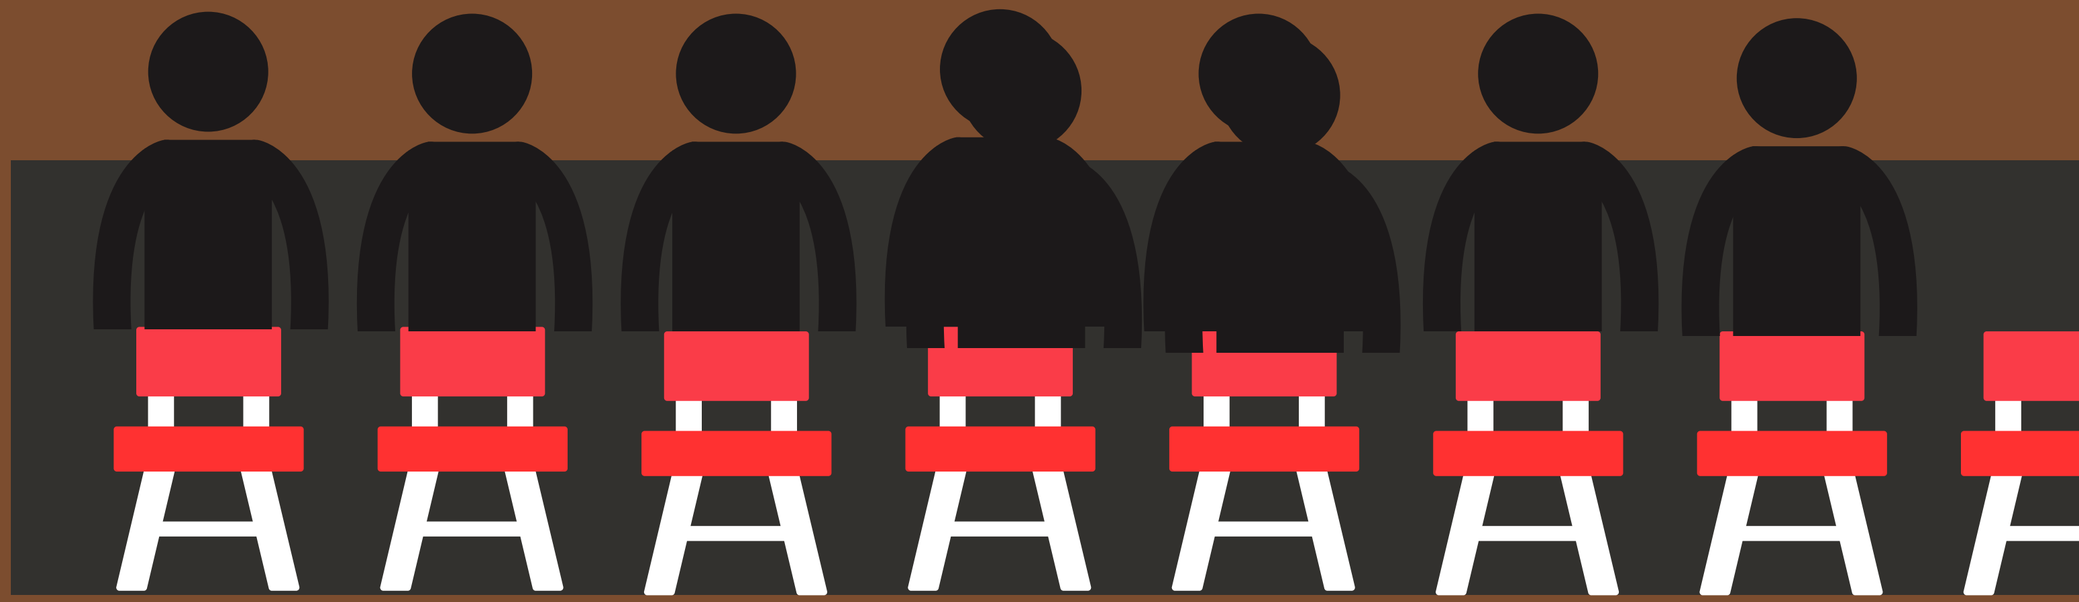
But you know this strategy will eventually lead to you not having enough space



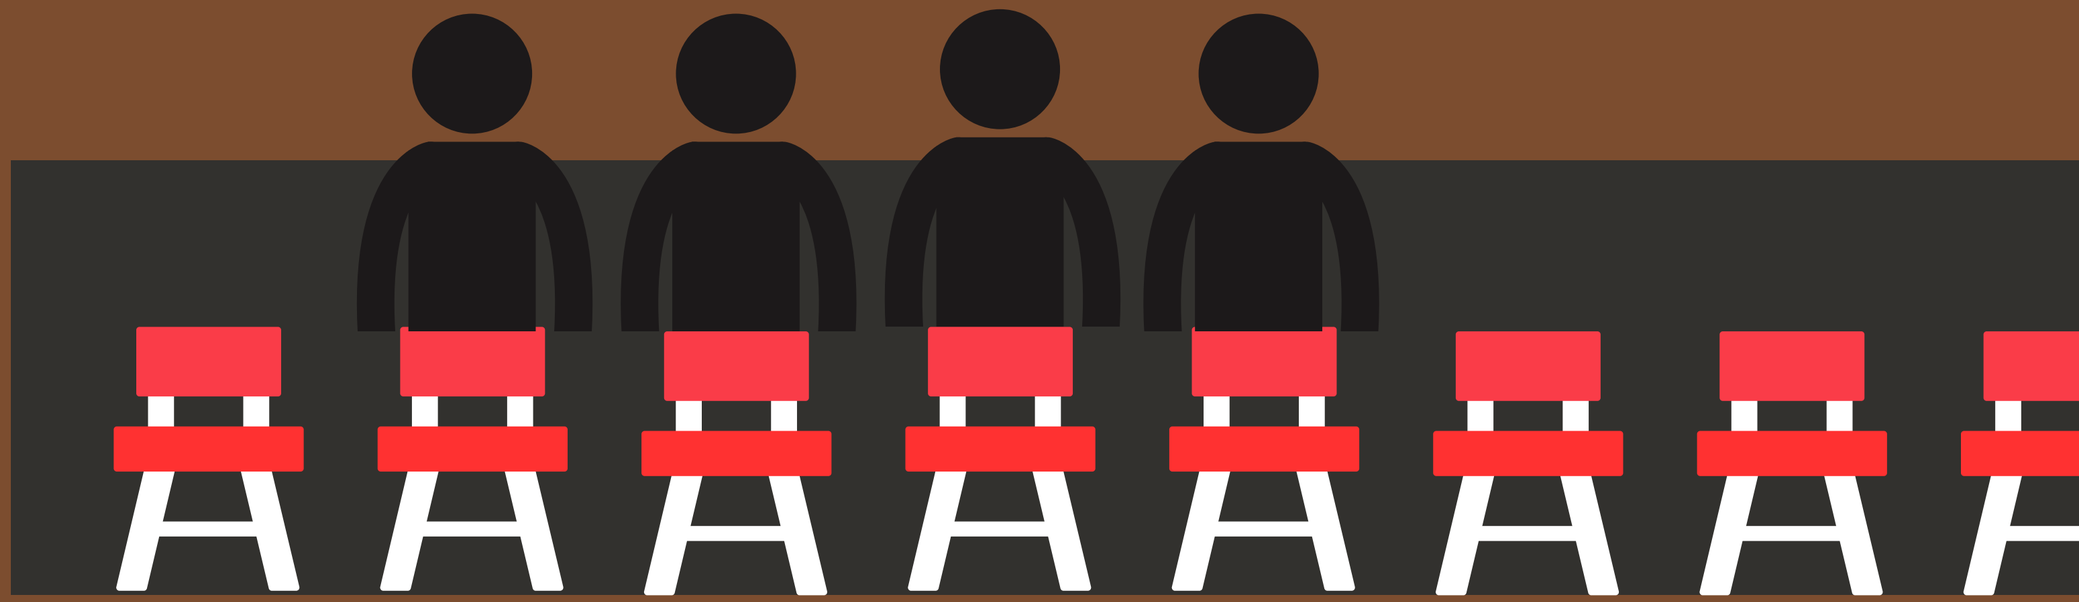


Luckily, you know people don’t stay at the bar forever.

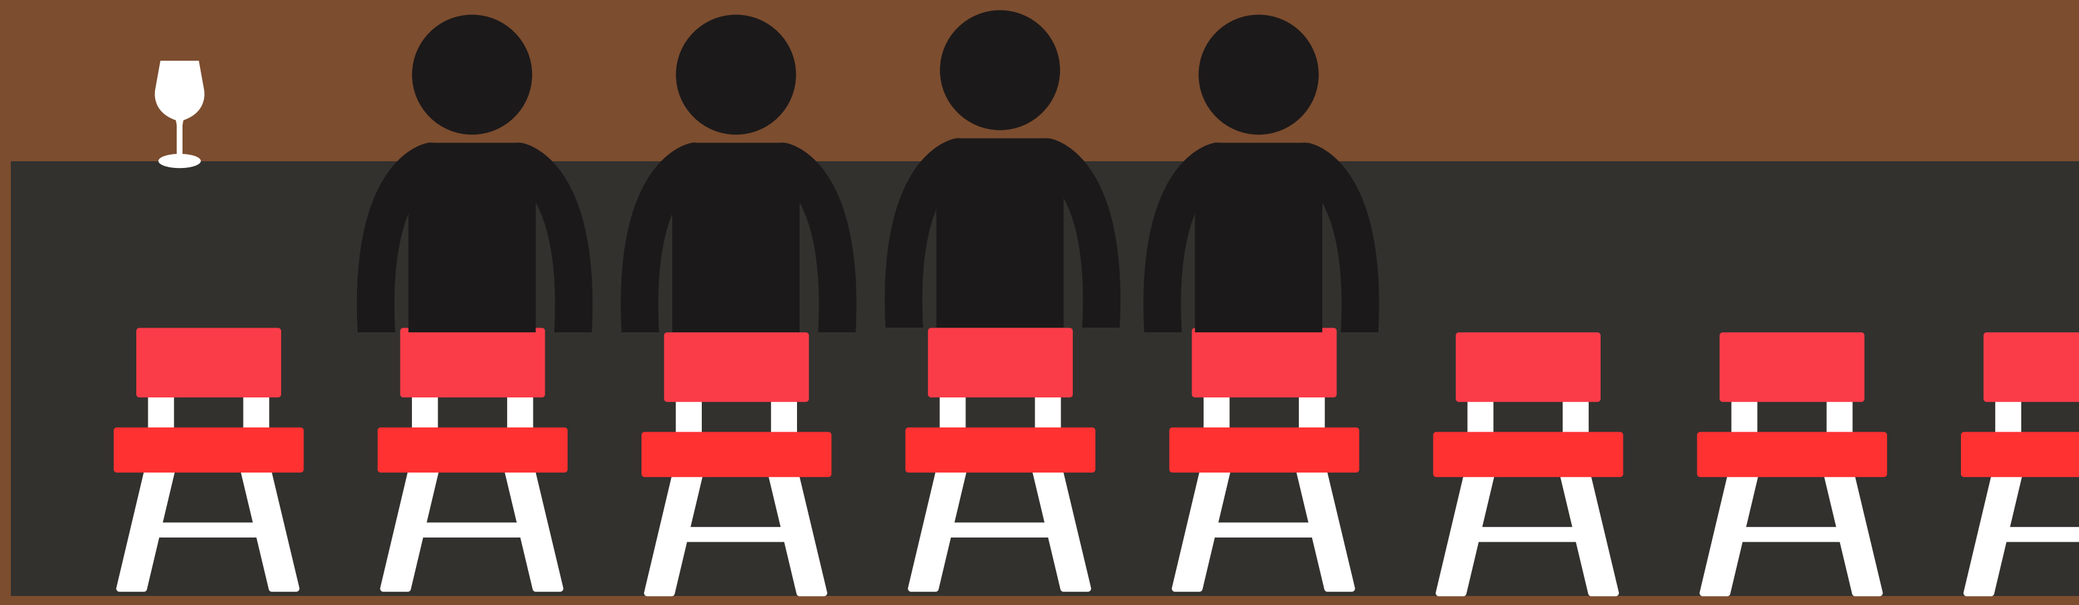
So you look to see if theres more space



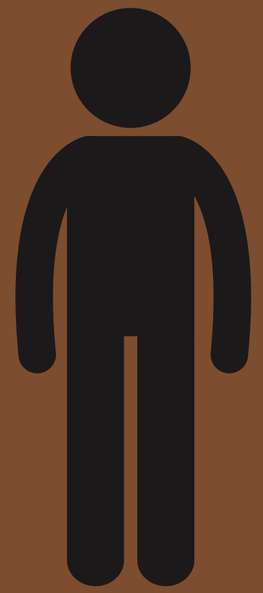
But you know you will soon run out of space if you keep doing this

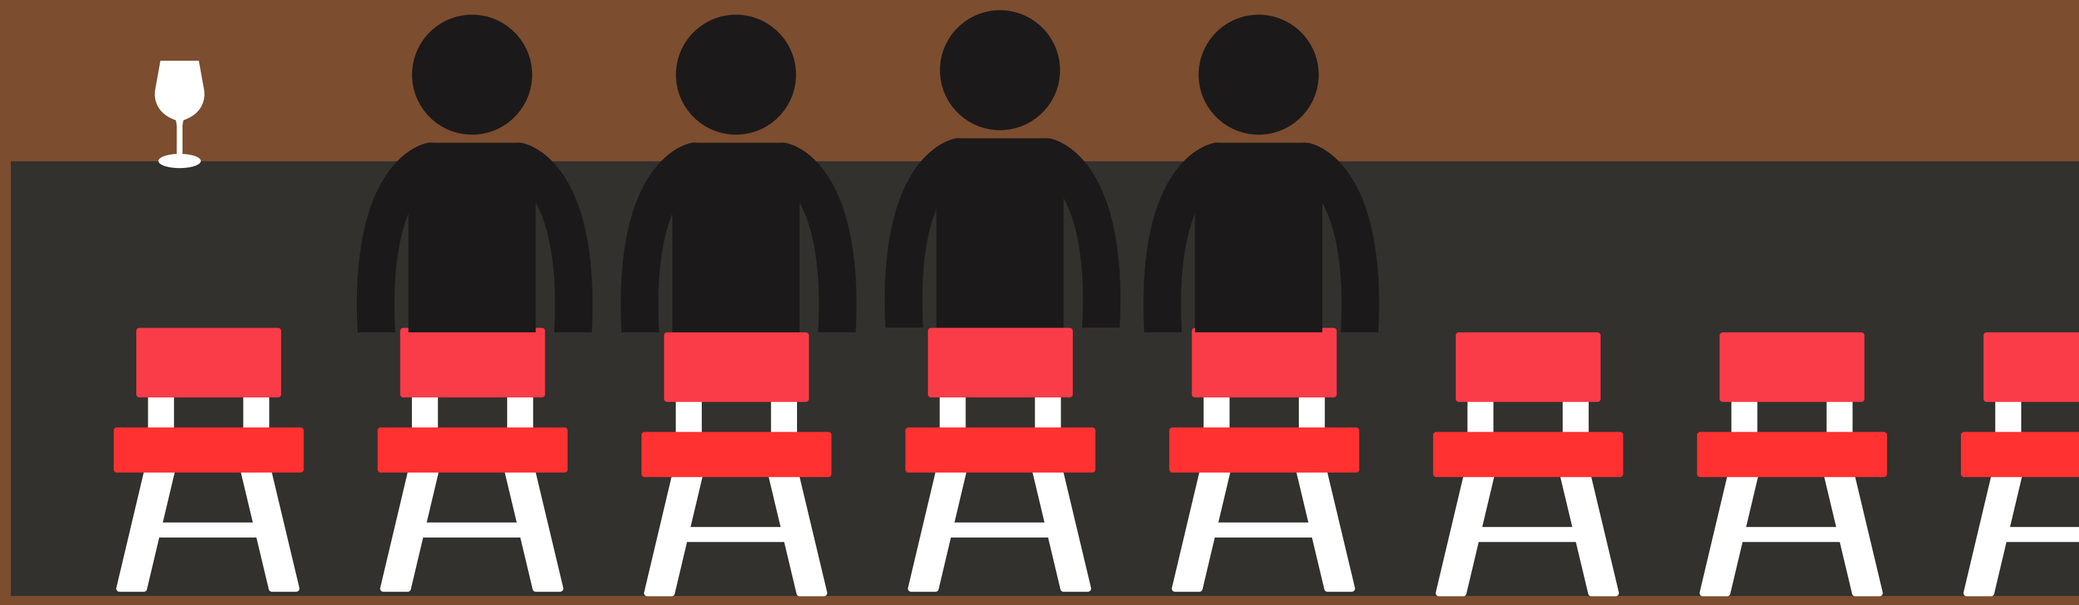


One person leaves

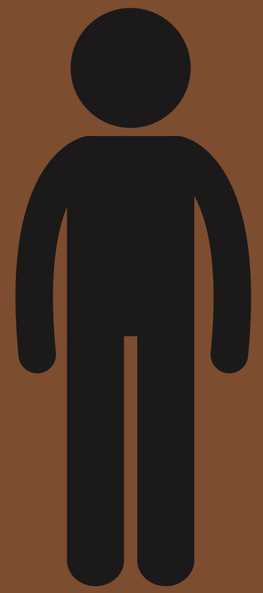


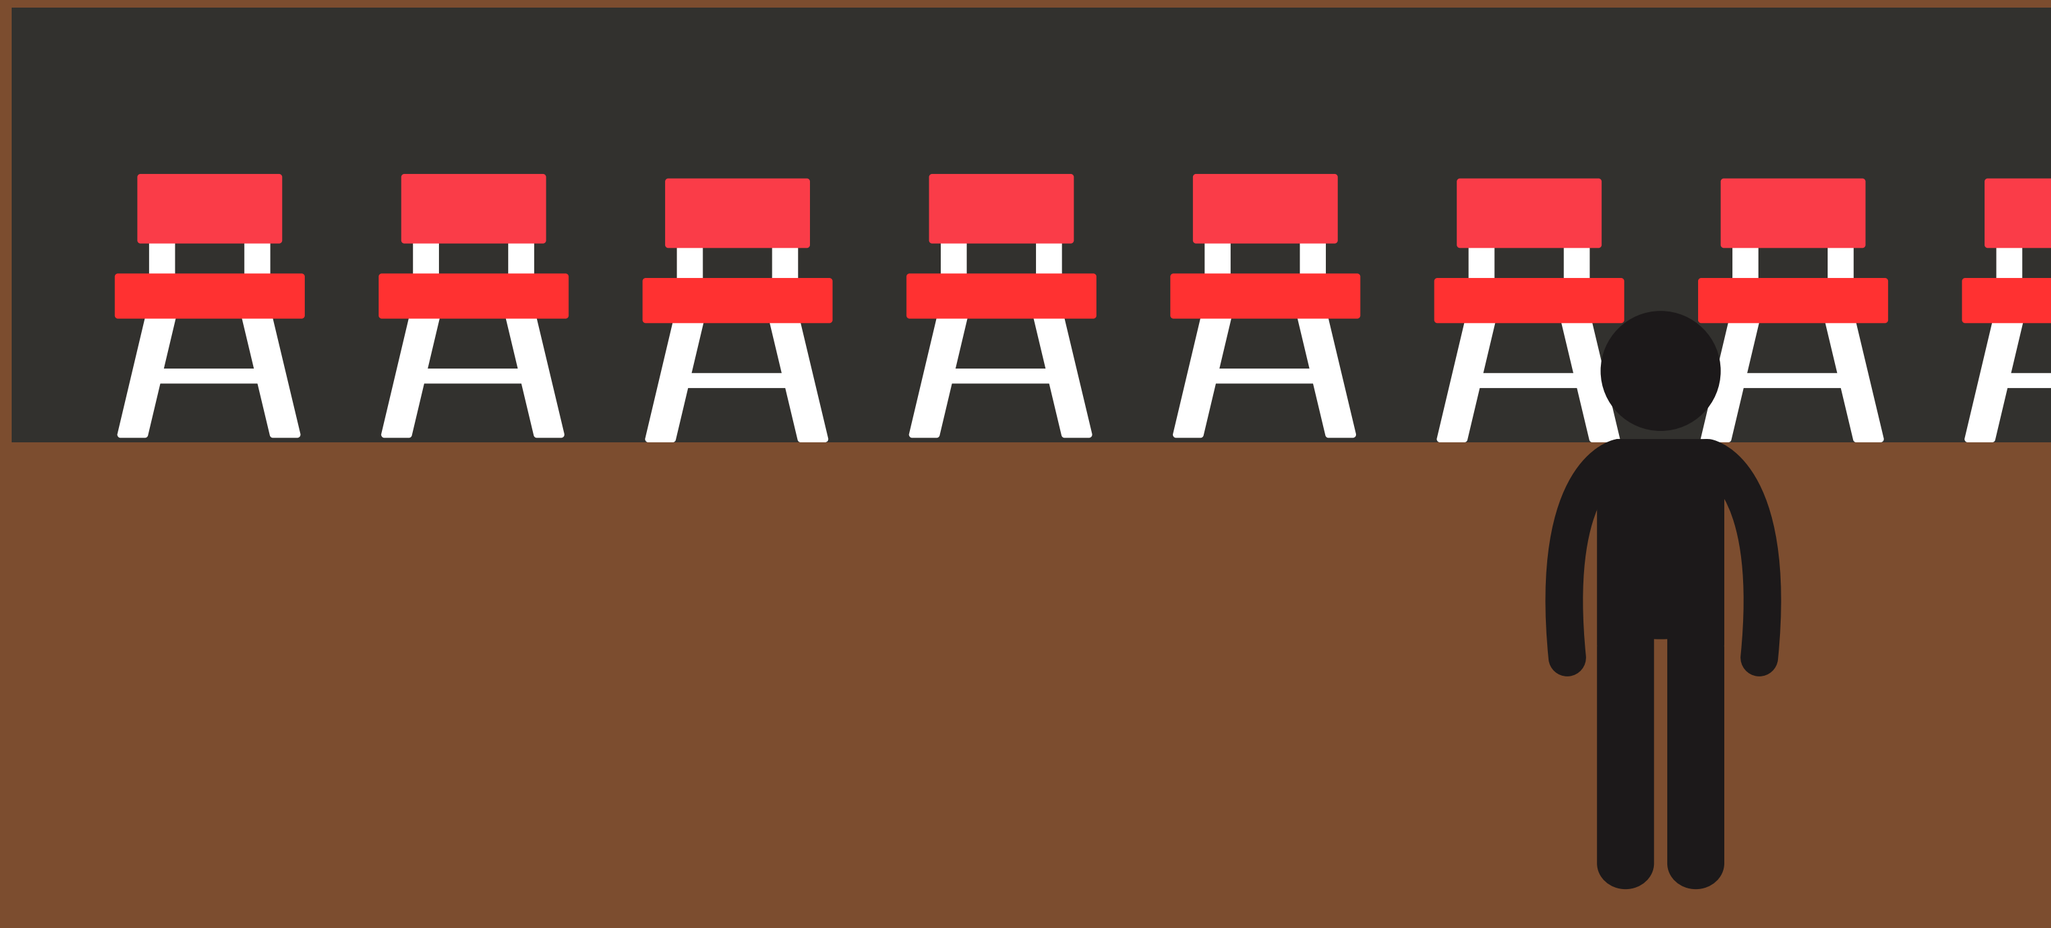
If another person comes in, you cannot seat them in their space, unless you are sure that they are done





If another person comes in, you cannot seat them in their space, unless you are sure that they are done





And you are tending a bar...
